Afterbrand

Every retired name, decided in context.

Afterbrand finds every page that still uses a retired product name, decides which mentions should change, and drafts the fix. A person approves every change before it ships.

Fusion → **Builder Code** | Publish → **Builder Content**

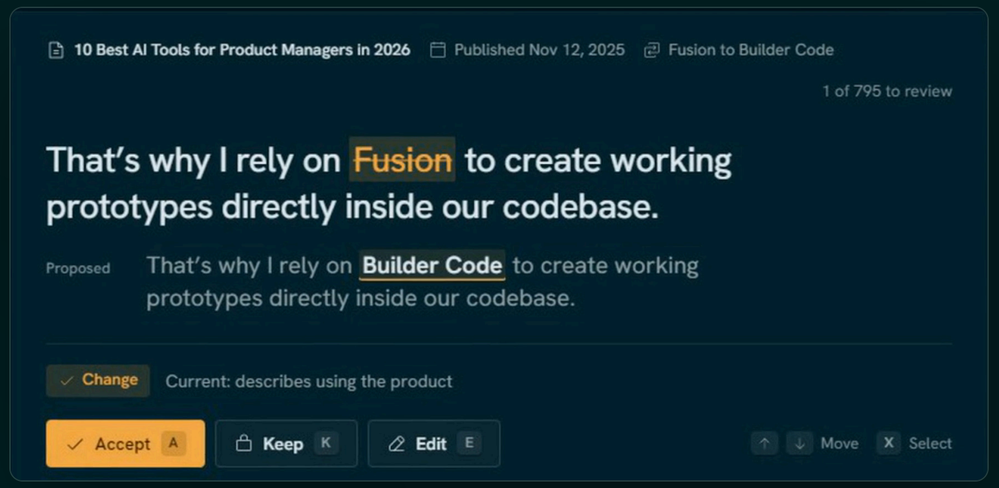

Builder renamed two products on Sept 10, 2026.

976

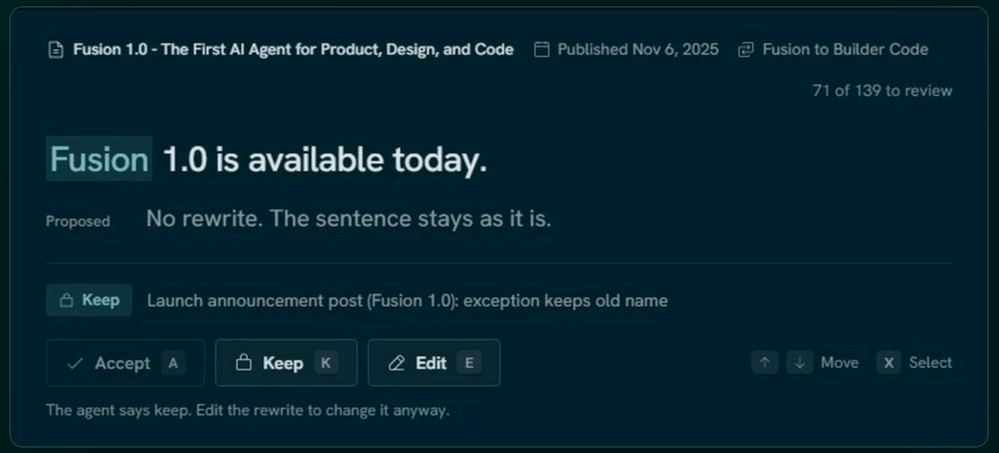

mentions of the old names, six weeks later

on its blog, in 132 of 537 posts (snapshot of Oct 25, 2026)

Launch posts keep the old name, and “publish” is also the verb on every other page, so each mention needs its own decision.

Change: the sentence describes the product people use today.

Keep: a launch announcement records what shipped at the time.

140 labeled mentions from 70 Builder blog posts

A wrong answer changes a mention that should stay, or keeps one that should change.

Find and replace

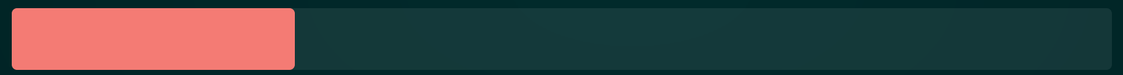

Changed all 35 mentions that should stay.

35 wrong

Strongest regex

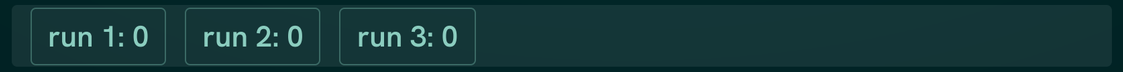

Changed 8 that should stay,
kept 1 that should change.

9 wrong

Afterbrand

Three runs, each with 0 wrong edits and 0 misses. Sent 5, 6 and 7 of the 140 to a person.

0 wrong

Labels: two language models, Claude Opus and Claude Fable, working separately from a written guideline without seeing the agent's output. Model under test: Claude Sonnet 5.5. Source: eval/results/report-test.md in the repo.

How a rename gets reviewed

01

Rules

The retired name, its replacement, the date it took effect and the exceptions, in plain language. The agent edits them through the same action.

02

Decisions

Code finds every sentence with a retired name. The agent decides Change, Keep or Needs you, with a one-line reason and a rewrite that code checks.

03

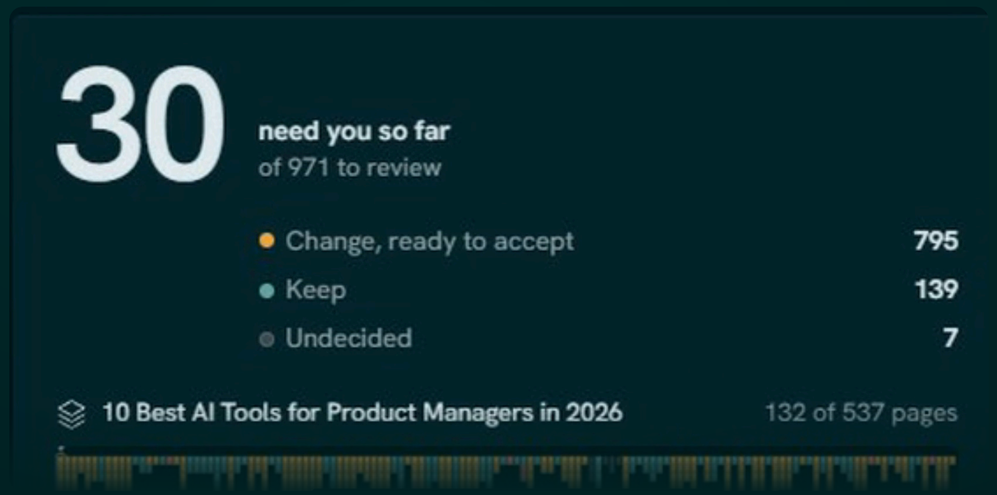

Review

A person accepts, keeps or edits, alone or in bulk. Say “never change launch posts” and the agent proposes the exception, then re-decides the rest once it is approved.

04

Publish

Also approved by a person. Changes to Builder pages go back as unpublished edits, so a live page changes only when someone publishes it in Builder.

From the recorded run: the agent decided all but 7 of the 971 mentions to review, and 30 wait for a person.

Every operation is one defineAction

The screen, the agent, Claude Code over MCP and the CLI call the same code. The business rules live inside the action, so no caller can skip them.

Approval by code

The batch code is the start of a SHA-256 over every sentence and rewrite in it. If any of them changes after staging, accepting is refused.

Agent teams

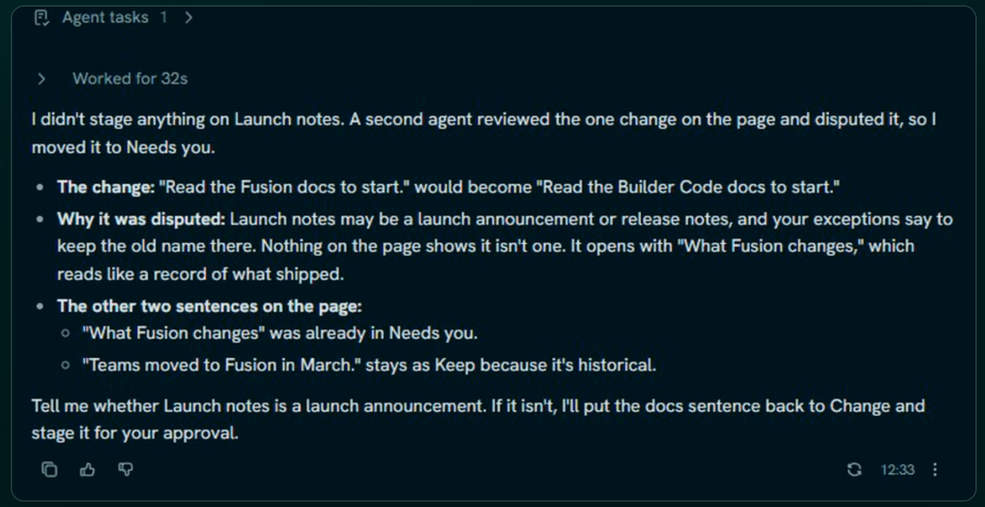

Before a batch reaches a person, a second agent re-reads it against the rules. Whatever it disputes goes to Needs you.

Exact undo

Undo restores the sentence at the position where it changed. Applying and undoing each run in one database transaction.

Automations

A rule change or a Builder publish emits an event, and an automation decides the findings it left pending.

From the recorded run: the reviewer disputed the only change on a page that reads like a launch post, so it went to a person.

A Builder publish is decided before anyone asks

12:30 pm

A page is published in Builder.

+10 s

The webhook brings it into Afterbrand.

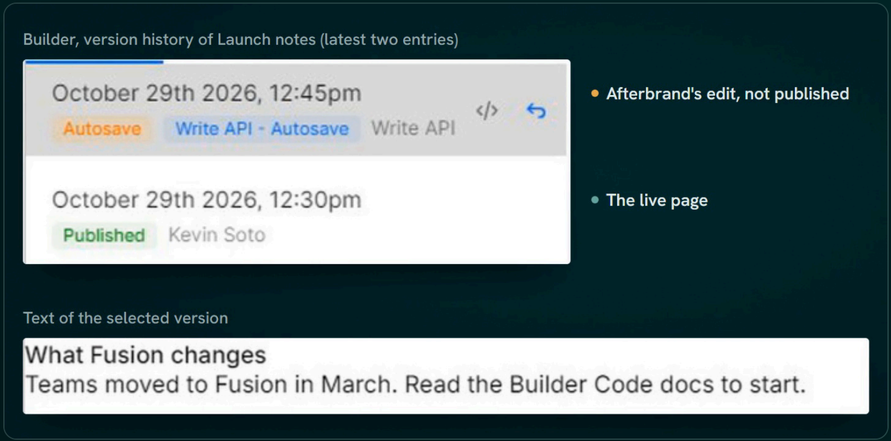

+28 s

An automation decides its three mentions.

The reviewer disputes the change. A person says the page is current.

12:45 pm

Approved by its batch code, it reaches Builder as an unpublished edit.

Builder’s version history after the run: Afterbrand’s edit waits as an autosave, and the published page keeps the old sentence until someone publishes it in Builder.

Recorded live on Oct 29, 2026, on a page made for the test. Times from the page’s history in Builder and the recording.

Built during the event

Oct 25 and 26

The first version, declared as existing work. It was built inside the submission window as first published; the start date later moved to Oct 27.

From the Agent-Native chat template, packages pinned at 0.220.0, to the mention finder, rewrite verifier, actions, decision skill, queue, MCP catalog and eval. The skill the eval measured has not changed since.

Commits 40cfc56 to 740d63a. Each hash on this slide opens its commit in the public repo.

From Oct 27

6344337	The queue leads with what needs a person; agent rule edits need approval
b6b456d	The agent stages a batch; a person approves it by its code
5b6280a	Publishing is bound to a code for exactly the accepted changes
620afe5	Undo restores the exact sentence; apply and undo are atomic
6ff4be4	Builder connector: import, unpublished edits, webhook on publish
c0d5a71	A second agent, spawned through agent teams, reviews every batch
96ad70c	Builder connector tested on a live space
5bf059b	The deploy starts with the library already decided
855de4a	The reply shows once with its follow-ups (framework fix, as a pnpm patch)
2827663	An early chat runs on Sonnet 5.5 under the deploy’s model lock
696b59a	Webhook and rule events reach automations on a serverless deploy
96f15bc	A publish sent without its text is read back from the content API

Limits, stated up front

The full list is in the README, section Limits.

- **The agent can be wrong.** Every change waits for a person, and the eval reports each error instead of a single score.
- **Zero wrong edits in 35 still leaves room.** The 95% Wilson upper bound on the wrong-edit rate is about 10%, and only 18 mentions come from posts published after the rename.
- **Both labelers are language models.** They followed the same guideline the agent’s skill encodes, so a rule both read the same wrong way would not show up as an error.
- **The eval scores decisions.** Rewrites are checked only by the code verifier.
- **The Builder connector ran end to end on a live space**, on entries made for the test.
- **One agent decides in batches.** Splitting a sweep across agent teams is not built.

Afterbrand

Every retired name, decided in context.
